DNS SERVICES

DNS HIERARCHY

Local/Name Servers:

- Every ISP has one
- Acts as proxy, forwards request to hierarchy if name-address not available in local cache
- Once a mapping is learned → cached with TTL

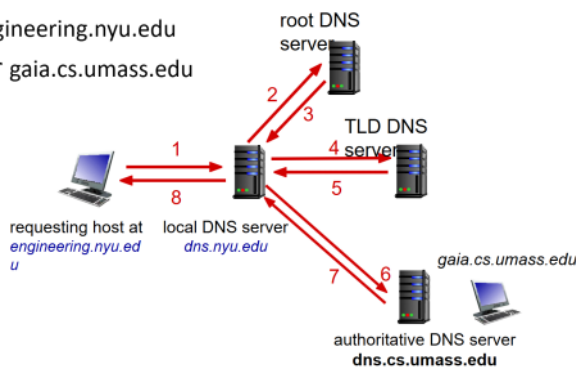

Disadvantage: May be out of date.

If host changes IP, will not be known until TTL expires

Example: host at engineering.nyu.edu
wants IP address for gaia.cs.umass.edu

Iterated query:

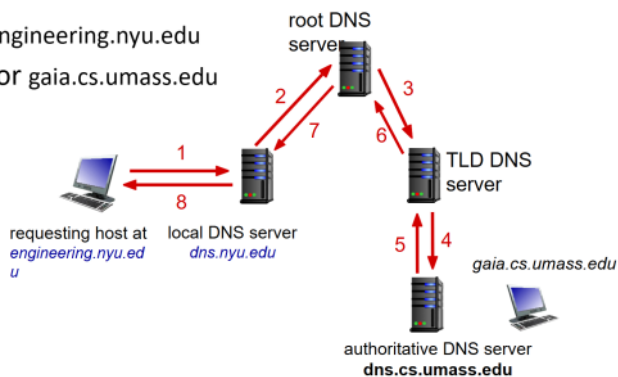

- contacted server replies with name of server to contact
- "I don't know this name, but ask this server"

Example: host at engineering.nyu.edu
wants IP address for gaia.cs.umass.edu

Recursive query:

- puts burden of name resolution on contacted name server
- heavy load at upper levels of hierarchy?

DNS RECORDS

DNS → distributed database containing resource records (RRs)

type = A

name: hostname

value: IP address

some-example.foo.com, 123.45.67.890, A

type = NS

name: domain (foo.com)

value: hostname of authoritative name server for domain

foo.com, dns.foo.com, NS

type = CNAME

name: some alias for canonical name

www.ibm.com → servereast.backup2.ibm.com

value: canonical name

ibm.com, servereast.backup2.ibm.com, CNAME

type = MX

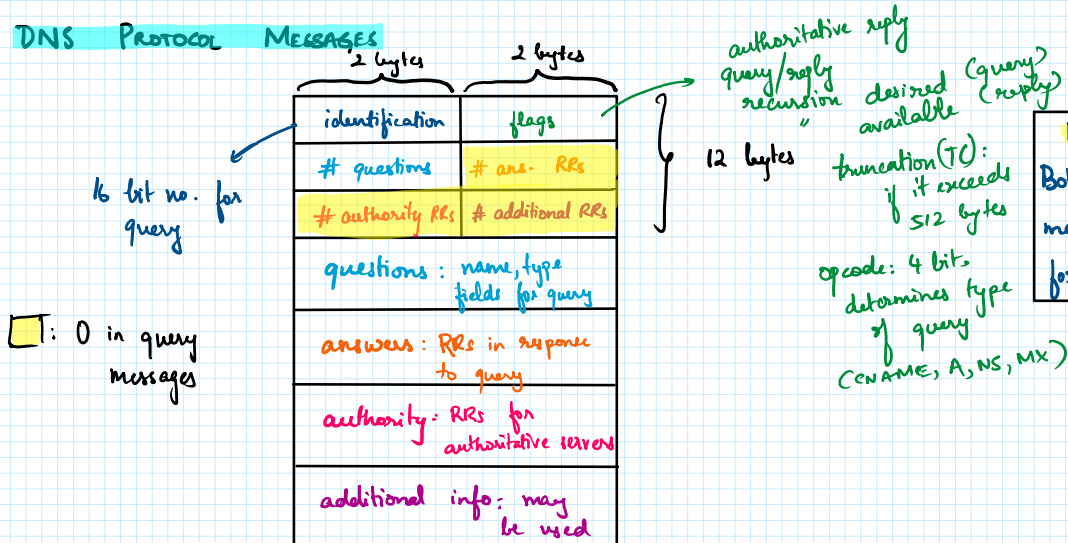

name: alias hostname

value: canonical name of mail servers associated with alias hostname

example.com, mail.example.com, MX

RR format: (name, value, type, TTL)

DNS Protocol Messages

Note:

Both DNS query and reply messages have the same format

☐: 0 in query messages
