2. Functional Programming

29 November 2023 08:33

FUNCTIONAL PROGRAMMING

- · Involves some sort of callback , not keywords
- · Constructs: map, filter, reduce, zip, lambola, keyword: used to create enonymous
- · Aims to reduce the number of lines as much as possible

MAP

mak ([function], [iterable])

Jakes each value from the iterable and passes that value through the specified function. The resulting values are stored in a lazy object of the class "map" (iterator object).

Noie: Multiple organis

You can specify multiple iterables in the map function, but the map function only iterates till the last element of the smaller iterable

```
list(map(lambda x: x+1,[1,2,3,4]))
[2, 3, 4, 5]
list(map(lambda x,y: x+y,[1,2,3,4],[2,3,4,5,6,7]))
[3, 5, 7, 9]
type((map(lambda x,y: x+y,[1,2,3,4],[2,3,4,5,6,7])))
<class 'map'>
```

When to use map: When number of elements in the output = no. of elements in input

FILTER

filter (Junctim, [iterable])

- · Checks for Boolean values
- · Values that return True for the function are stored into an iterator

```
tuple(filter(lambda x:x[0]=="a", ["advaith", "magic", "cricket", "arts"]))
('advaith', 'arts')
```

· If function is None, then it returns all values that are True

```
list(filter([1,2,4,-3,-5,0,""]))
Traceback (most recent call last):
```

File "<pyshell#11>", line 1, in <module>
 list(filter([1,2,4,-3,-5,0,""]))
TypeError: filter expected 2 arguments, go

When to use filter: When no. of elements in output

in Domante in inhealt

```
Traceback (most recent call last):
   File "<pyshell#11>", line 1, in <module>
        list(filter([1,2,4,-3,-5,0,""]))
TypeError: filter expected 2 arguments, got 1
list(filter(None,[1,2,4,-3,-5,0,""]))
[1, 2, 4, -3, -5]
```

no of elements in input

REDUCE

import functools functools reduce ([function], [iterable], [inital value])

- · Reduces an iterable to a single value
- · Junction takes two arguments; two elements are taken at once into the function which returns some value. This continues progressively till the end of the iterable
- · Initial value (if specified) is taken as the first argument of the function before going through iterators

```
from functools import reduce
reduce(lambda x,y: x+y, [1,2,3,4,5,6,7,8,9,10])
55
reduce(lambda x,y: x+y, [1,2,3,4,5,6,7,8,9,10],100)
155
reduce(lambda x,y:x+y[0],["Advaith","S","Kumar"],"")
'ASK'
```

LAMBDA

- · Used to create anonymous, inline functions
 - lambda vart, varz..: [seeturn value from function without specifying "return"]
- * You can also create named functions by assigning a lambda function as the value of some variable.

ZIP
